Identification of Unknowns in a Chemical Spill
Unknown Volatile Organic Compounds

Volatile chemicals pose the greatest risk to personnel because of the potential for escape into the atmosphere and breathing zone. PID detectors and gas monitors can provide an indication that something is present, but cannot aide in identification. The ability to bring a portable GC/MS to the sample provides a fast, effective means to identify unknown volatile compounds and quantify the risk factor.

HAPSITE® was used in this application to sample the headspace above a container filled with an unknown liquid. Prior sampling with a chemical identification kit could not provide conclusive identification of the substance. Within five minutes of taking the sample, the NIST mass spectral database search routine had confirmed the compound as 1,1,1-Trichloroethane.

NIST (National Institute of Standards and Technology) mass spectral search results for GC/MS peak at 2 minutes 19 seconds, confirmed as 1,1,1-Trichloroethane.
